I have a very basic problem here. I am currently learning C and am doing some exercises where you need to implement a function that takes 2 ints, then it swaps them, then return the swapped number. I have not learned what the correct syntax is for that yet. My first thought was just to write a swap function that takes a pointer to an int, then I can pass the address of the int to be swapped. Like so: `void swap(int* x, int* y) { int temp = *x; *x = *y; *y = temp; }` My issue is that I don't think I'm implementing this correctly, because I'm always getting incorrect answers in my homework, or the output is 'Illegal instruction' So the question is: How do you implement a swap function correctly in C? A: `void swap(int *x, int *y) { int temp = *x; *x = *y; *y = temp; }` swap will only work correctly if *x and *y are valid pointers. For example, if *x is an address of a memory block, then you should make sure that that block was allocated with malloc or something like that. Other than that, there is no problem with your code. Beware, however, of possible problems with signed and unsigned types. If one of the parameters is signed, then the other one should be unsigned. A: `void swap(int *x, int *y) { int temp = *x; *x = *y; *y = temp; }` 1. Field of the Invention This invention relates to a pressure 2d92ce491b
